$$y[n] = h[n] * a^n u[n]$$

Project directed by Prof. Edward A. Lee and co-directed by Prof. David G. Messerschmitt

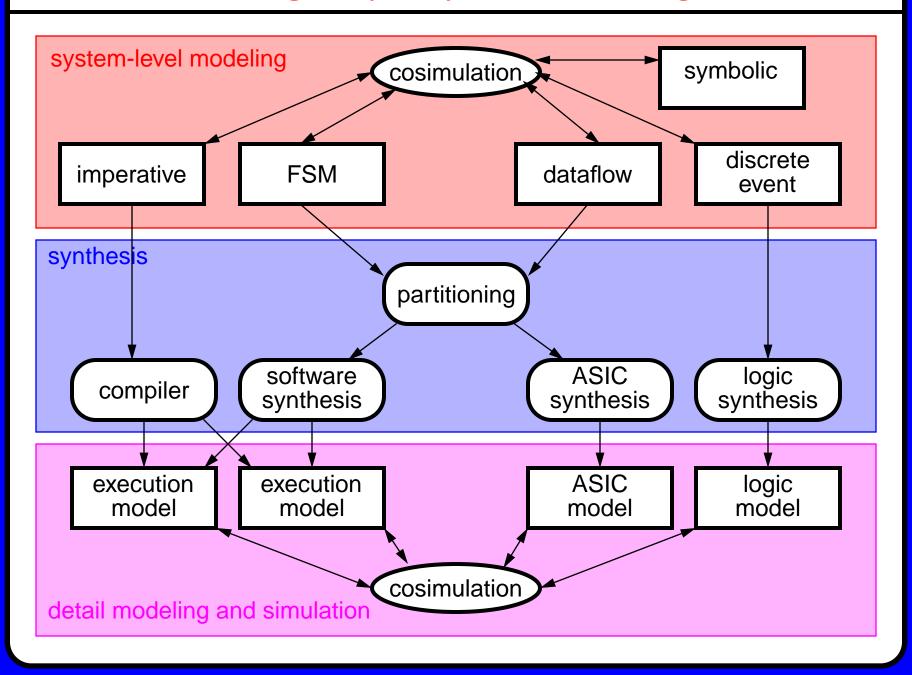

A Typical Embedded Signal Processing System

Heterogeneity in System-Level Design

Ptolemy Project

Design Methodologies for Heterogeneous Systems

- Formal models of computation
- Hierarchical compositions of models form complex systems
- Synthesis and partitioning algorithms
- Laboratory to test design methodology is the Ptolemy software environment

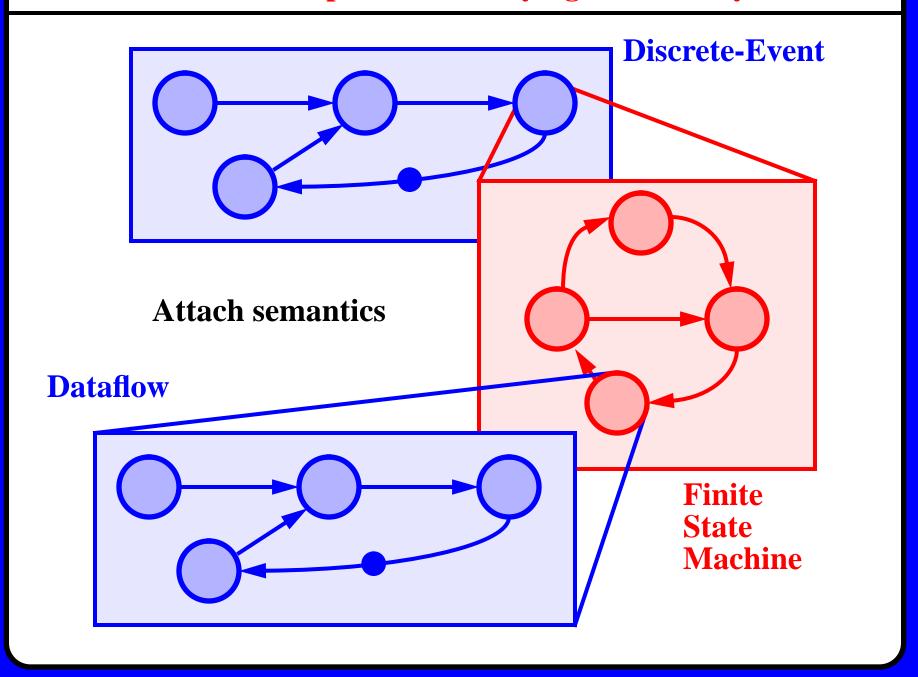

Claudius Ptolemaeus

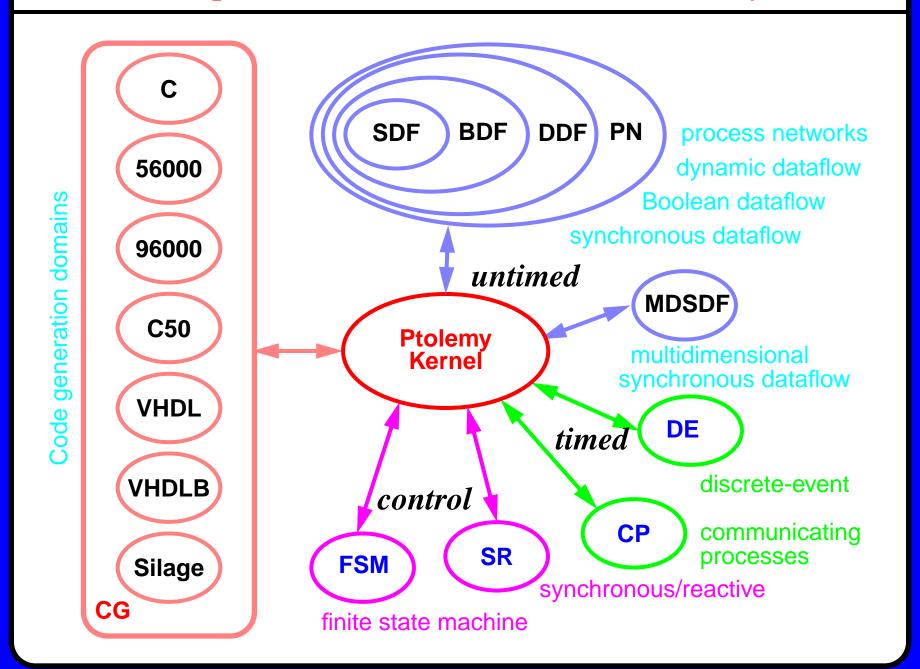

Personnel

- Directors: Profs. Edward Lee and David Messerschmitt
- Staff: 4 post-doctoral, 1 software manager, 2 administrative
- Students: 12 graduate and 3 undergraduate

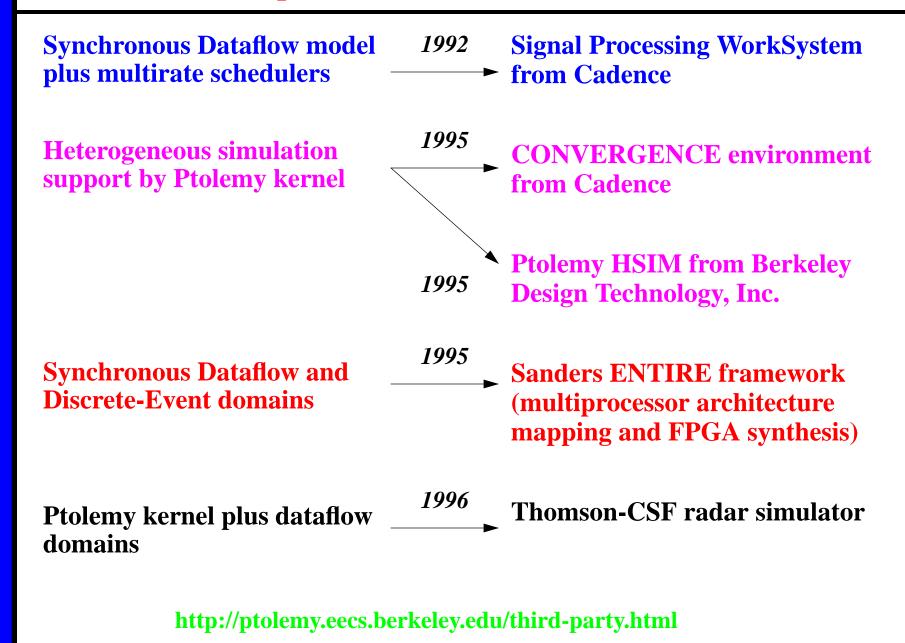

Hierarchical Graphs As Underlying Abstract Syntax

Computational Models (Domains) in Ptolemy

Impact on Industrial CAD Tools

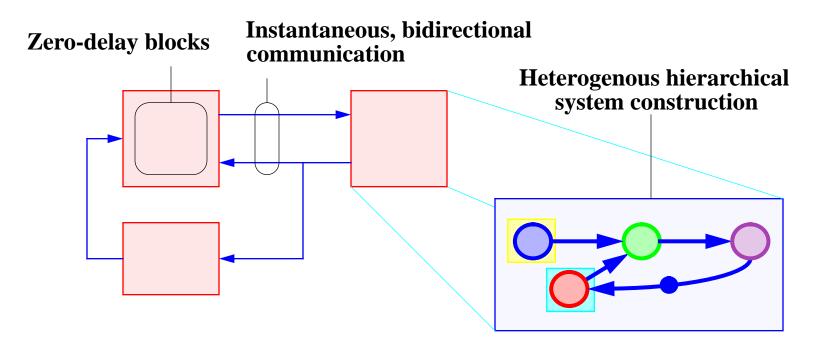

Our Current Research in System-Level Design

| | Topic | Example |
|---------------|--------------------------------|-----------------------------------|
| Specification | System optimization | System rearrangement |
| | Scalable systems | Higher-order functions |
| | Visual languages | Tycho |
| | Formal semantics | Tagged signal model |
| Simulation | Dataflow models of computation | Multidimensional dataflow |
| | Control models of computation | Synchronous/reactive |
| | Cosimulation | Mixed signal simulation |
| | Native signal processing | UltraSparc visual instruction set |
| Synthesis | Partitioning | Hardware/software codesign |
| | Uniprocessor scheduling | Program/data code minimization |
| | Multiprocessor scheduling | Hierarchical scheduling |
| | Distributed systems | Network of workstations |

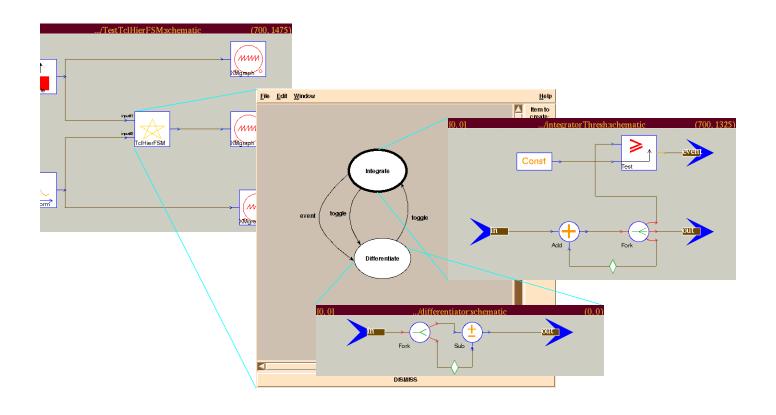

Synchronous/Reactive Model of Computation

- Synchronous means that computations occur "instantaneously" at integer clock ticks (Lustre, Signal)
- Reactive means that the model responds to the environment at the speed of the environment (Esterel, StateCharts)
- Modules are monotonic functions operating on complete partial orders
- Execution proceeds by iterating towards the fixed-point compile-time analysis finds an execution order guaranteed to produce the least fixed-point
- Schedules determined at compile-time in polynomial time

Mixing FSMs and Dataflow Models of Computation

- Each Finite State Machine (FSM) has a single thread of control
- Arranging FSMs in a nested tree specifies hierarchical FSMs
- Arbitrary mixing of FSMs and dataflow models of computation captures captures the 21 variants of Statecharts
- Formal analysis (verification) possible due to finite state

Vision for Common Operating Environments

Requirements to avoid

- Avoid one monolithic standard
- Avoid standardizing on one general purpose language
- Avoid one specification format

Requirements to include

- Support of domain-specific models of computation/tools
- Support imperative and declarative styles of programming
- Support multiple specification formats, such as directed acyclic graphs, textual languages, algebraic descriptions
- Support back annotation
- Support general frameworks for tools to interface with
- Support cosimulation of arbitrary levels of abstraction
